Problem Set 6

Due Wednesday, October 13

Problem 1: Show that

$$v(t) = Ke^{-\alpha t} \sin(\omega_d t + \phi)$$

is the general solution of the differential equation

$$\frac{d^2v}{dt^2} + 2\alpha \frac{dv}{dt} + \omega_0^2 v = 0 \quad \text{where} \quad \omega_0 > \alpha$$

if $\omega_d = \sqrt{\omega_0^2 - \alpha^2}$. The method will be outlined in the following parts.

(A) Show that

$$\frac{dv}{dt} = -\alpha Ke^{-\alpha t} \sin(\omega_d t + \phi) + \omega_d Ke^{-\alpha t} \cos(\omega_d t + \phi)$$

(B) Show that

$$\frac{d^2v}{dt^2} = \alpha^2 Ke^{-\alpha t} \sin(\omega_d t + \phi) - 2\alpha\omega_d Ke^{-\alpha t} \cos(\omega_d t + \phi) - \omega_d^2 Ke^{-\alpha t} \sin(\omega_d t + \phi)$$

(C) Substitute the expressions for $\frac{d^2v}{dt^2}$, $\frac{dv}{dt}$ and v into the differential equation. Group the coefficients of the sine and cosine terms and equate each group to zero. You should be left with two algebraic equations. Show that the equations hold if $\omega_d = \sqrt{\omega_0^2 - \alpha^2}$.

(D) You have found the general solution for the differential equation given in the problem statement. Given this solution, find the solution for the differential equation

$$\frac{d^2v}{dt^2} + \omega_0^2 v = 0$$

(E) Show that the solution for the differential equation found in the previous part can be converted to the form

$$v(t) = A \sin(\omega_0 t) + B \cos(\omega_0 t)$$

Hint: $\sin(x + y) = \sin x \cos y + \cos x \sin y$.
