

Random Notes on C-shell programming.

1.0 Useful Shell variables:

Knowledge of these variables helps to make a pleasant environment :-) !!. Some of these may be needed in shell scripts also. Typically these are set in the .cshrc file.(For example savehist , history, path etc are usually set in .cshrc)

| | |
|-----------|--|
| argv | Array of arguments supplied. \$<n> is for nth argument. \$* is for all arguments. \$#argv has the number of arguments. |
| noclobber | If set, restricts overwriting of files by redirection. If file needs to be overwritten, then redirection symbol ">!" (instead of ">") should be used. |
| cwd | Variable containing the name of current directory. |
| ignoreeof | Disables logging out with ctl-D. |
| nobeeep | Disables beeping while file name completion. |
| nonomatch | Error message are not given when file name doesnt match. |
| prompt | string to be used as primary prompt. |
| path | contains the directory names where executables need to be searched. Ex - set path=(~/bin/sparc-sun-solaris2.6/ \$path /users/guru/utills) will add other two directories to earliar path. |
| history | No of commands in history |
| savehist | No of commands from history to be saves while quitting c-shell. |
| home | Contains the home directory. ~ refers to this directory. cd < without any arguments> will change the current directory to this directory. |
| shell | the file where cshell resides. |
| filec | Enables file name completion with ctl-D and ESC. |

2.0 An example :For putting host and directory in prompt.

For command
number

alias cd 'cd \!*;set prompt=(`hostname`"@"\$pwd" !% ")'

For the input
that is put after the
command-!*
\ is for escaping !

3.0 First line of the shell script :

is typically `<path>/csh [-bcefnstvVxX] [argument ...]`. This is needed as by default all the commands in the scripts are treated to be of bash. In order for interpreter to treat the commands to be of c-shell , the path of csh should be given in comments in the first line of shell-script. The letters followed by “- “ are the options. The functionality of each of the options are tabulated here:

| | |
|------|--|
| | |
| -e | Exit if a command terminates abnormally or yields a nonzero exit status |
| -f | don't read .cshrc file/ .login file . |
| -i | Forced interactive. Prompt for command line input, even if the standard input does not appear to be a terminal . |
| -n | Parse (interpret), but do not execute commands. This option can be used to check syntax etc. |
| -s | Take commands from the standard input. |
| -v/V | Echo commands without values of variables substituted. |
| -x/X | echo commands after all substitutions and just before execution. |
| -b | Blocks all the further options. |
| | |

4.0 File inquires:

The boolean information about files can be got by file inquires. A typical use is - if(<file_inquiry>) then....

different file inquiries are tabulated here:

| | |
|-------------|---|
| -r filename | True if the user has read access. |
| -w filename | True if the user has write access. |
| -x filename | True if the user has execute permission |
| -e filename | True if filename exists. |
| -o filename | True if the user owns filename. |
| -z filename | True if filename is of zero length |
| -f filename | True if filename is a plain file. |
| -d filename | True if filename is a directory. |

5.0 Arithmetical operations :

> + - * / and % have their usual meaning. **But should have a space on either side of the operator .**

6.0 Logical operators:

For all the operations use **braces appropriately** to avoid any unwanted results!!

| | | |
|----|----|---------|
| >> | << | ! |
| & | && | ^ |
| | | == / != |

7.0 An example :

The following example is for creating a directory with all files linked to those of input dir.

```

#!/bin/csh -f
rm -rf {$1}_link
cp -r $1/ {$1}_link/
cd {$1}_link
foreach vec_name (`find . -name "*" -print`)
  if( -f $vec_name) then
    chmod +w *
    \rm -f $vec_name;
    ln -s {$1}/{$vec_name} $vec_name
  endif
end

```

Checking if file exists..

use a flower bracket if a variable is used for specifying the path.

\ is for using an unaliated rm command.

A command substitution is used.

8.0 file name manipulation:

The following table lists different ":" commands and their results.

| | |
|--|--|
| set dir = /users/guru/sudo_random_data/psdo_data.c | |
| echo \$dir | /users/guru/sudo_random_data/psdo_data.c |
| echo \$dir:h | /users/guru/sudo_random_data |
| echo \$dir:t | psdo_data.c |
| echo \$dir:r | /users/guru/sudo_random_data/psdo_data |
| echo \$dir:e | c |
| echo \$dir:q | /users/guru/sudo_random_data/psdo_data.c |
| echo \$dir:x | /users/guru/sudo_random_data/psdo_data.c |

9.0 Syntax of some of the commands:

Set commands:

```
set var = value
setenv var value
```

Control statements:

```
if (expr) command
```

```
if(expr) then
# commands.
endif
```

```
if(expr) then
# commands.
else
# commands
endif
```

```
foreach var (list)
#commands that can use $var.
#command break will exit the loop
end
```

```
while (expr)
#commands
#command break will exit the loop
end
```

```
switch (var)
case val1:
#commands
breaksw
case val2:
#commands
breaksw
```

```
....
default:
#commands
breaksw
```

```
endsw
```
