STANDARD C LANGUAGE

The following notations are used:
[ ]--enclosed item is optional; fn--function; b--block; rtn--return; ptd--pointed; ptr--pointer; expr--expression; TRUE--non-zero value; FALSE--zero value.

BASIC DATA TYPES

char	Single character (may signed or unsigned)
unsigned char	Non-negative character
short	Reduced precision integer
unsigned short	Non-negative reduced precision integer
int	Integer
unsigned int	Non-negative integer
long	Extended precision integer
unsigned long	Non-negative extended precision integer
float	Floating point
double	Extended precision floating point
long double	Extended precision floating point
void	No type; Used for denoting: 1) no return value from fn 2) no argument of fn 3) general pointer base

ARITHMETIC CONVERSION OF DATA TYPES

1. If either operand is long double the other is converted to long double.
2. If either operand is double, the other is converted to double.
3. If either operand is float, the other is converted to float.
4. All char and short operands are converted to int if it can represent the original value; otherwise it is converted to unsigned int.
5. If either operand is unsigned long the other is converted to unsigned long.
6. If the two operands are unsigned int and long and long represent all values of type unsigned int, the common type is long; otherwise it is unsigned long.
7. If either operand is long the other is converted to long.
8. If either operand is unsigned int the other is converted to unsigned int.
9. If this step is reached, both operands must be int.

STATEMENT SUMMARY

STATEMENT	DESCRIPTION
{ *local_var_decl* *statement* ... **}**	Block. The *local_var_decl* (local variable declarations) is optional.
break;	Terminates execution of **for**, **while**, **do**, or **switch.**
continue;	Skips statement that follow in a **do**, **for**, or **while**; then continues executing the loop.
do *statement* **while (***expr***);**	Executes *statement* until *expr* is FALSE; *statement* is executed at least once.
expr;	Evaluates *expr* ; discards result.
for (*e1***;***e2***;***e3***)** *statement*	Evaluates expr *e1* once; then repeatedly evaluates *e2*, *statement*, and *e3* (in that order) until *e2* is FALSE; eg: **for (i=1; i<=1Ø; ++i) ...;** note that *statement* will not be executed if *e2* is FALSE on first evaluation; *e1* ,*e2* and *e3* are optional; *e2=1* assumed when omitted.
goto *label*;	Branches to statement preceded by *label*, which must be in same function as the **goto.** eg.: **int Fn(void) {** **... goto write; ...** **write: print("here am I"); ...}**
if (*expr***)** *statement*	If *expr* is TRUE, then executes *statement;* otherwise skips it.
if (*expr***)** *statement1* **else** *statement2*	If *expr* is TRUE, then executes *statement1;* otherwise executes *statement2.*
;	Null statement.No effect.eg.: **while (t[i++]);**
return *expr*;	Returns from function back to caller with value of *expr* ; *expr* is omitted in **void** functions.
switch (*expr***)** **{ case** *const1***:** *statement* ... **break;** **case** *const2***:** *statement* ... **break;** ... **default:** *statement* **... }**	*expr* (must be an integer expression) is evaluated and then compared against integer constant exprs *const1*, *const2*, ... If a match is found, then the statements that follow the case (up to next **break,** if supplied) will be executed. If no match is found, then the statements in the **default** case (if supplied) will be executed.
while (*expr***)** *statement*	Executes *statement* as long as *expr* is TRUE; statement might not be executed if *expr* is FALSE the first time it's evaluated.

TYPE DEFINITION

typedef is to assign a new name to a data type. To use it make believe you're declaring a variable of that particular data type. Where you'd normally write the variable name, write the new data type name instead. In front of everything, place the keyword typedef. For example:

```
/* define type COMPLEX */
  typedef struct
    {
      float real;
      float imaginary;
    } COMPLEX;
/* declare variables with new type COMPLEX */
  COMPLEX c1, c2, sum;
```

CONSTANTS

char	' '		'a' '\n'
char string	" "		"hello" ""
float	…f,…F	(1)	7.2f 2.e-15F -1E9f .5F
double		(1)	7.2 2.e-15 -1E9 .5
long double	…l,…L	(1)	7.2l 2.e-15l -1E9L .5L
enumeration		(2)	red january monday
int			17 -5 Ø
long int	…l,…L	(3)	25ll 1ØØL
unsigned int	…u,…U		17u 5U Øu 65535u
hex integer	Øx,ØX		ØxFF ØXff ØxAØØØl
octal int	Ø		Ø777 Ø1ØØU Ø573ul

NOTES:
1. Decimal point and/or scientific notation.
2. Identifiers previously declared for an enumerated type; value treated as int.
3. Or any int too large for normal int

TYPE QUALIFIERS

const	Constant object, cannot be altered by the program.
volatile	External hardware or software can alter the variable, no optimalization.

OPERATORS

OPERATOR	DESCRIPTION	EXAMPLE	ASSOCIATION
++	Postincrement	ptr++	
--	Postdecrement	count--	
[ ]	Array element ref	values [1Ø]	⇒
( )	Function call	sqrt (x)	
.	Struct member ref	child.name	
->	Ptr to struct member	child_ptr->name	
sizeof	Size in bytes	sizeof child	
++	Preincrement	++ptr	
--	Predecrement	--count	
&	Address of	&x	
*	Ptr indirection	*ptr	⇐
+	Unary plus	+a	
-	Unary minus	-a	
~	Bitwise NOT	~Ø77	
!	Logical negation	! ready	
(*type*)	Type conversion / casting	(float) total/n	
*	Multiplication	i * j	
/	Division	i / j	⇒
%	Modulus	i % j	
+	Addition	value + i	⇒
-	Subtraction	x - 1ØØ	
<<	Left shift	byte << 4	⇒
>>	Right shift	i >> 2	
<	Less than	i < 1ØØ	
<=	Less than or equal to	i <= j	⇒
>	Greater than	i > Ø	
>=	Greater than or eq to	count >= 9Ø	
==	Equal to	result == Ø	⇒
!=	Not equal to	c != EOF	
&	Bitwise AND	word & Ø77	⇒
^	Bitwise XOR	word1 ^ word2	⇒
|	Bitwise OR	word | bits	⇒
&&	Logical AND	j>Ø && j<1Ø	➔
||	Logical OR	i>8Ø || ready	➔
? :	Conditional operator	a>b ? a : b If **a** greater than **b** then *expr*=**a** else **b**	⇐
= *= /= %= += -= &= ^= |= <<= >>=	Assignment operators	count += 2 It is equal to count=count+2	⇐
,	Comma operator	i=1Ø , j=Ø	➔

NOTES:

Operators are listed in decreasing order of precedence.
Operators in the same box have the same precedence.
Associativity determines: ⇒ grouping; ➔ order of evaluation for operands with the same precedence:
(eg: **a = b = c;** is grouped right-to-left, as: **a = (b = c);**).

PREPROCESSOR STATEMENTS

STATEMENT	DESCRIPTION
#define *id text*	*text* is substituted for *id* wherever *id* later appears in the program; (eg: **#define BUFFERSIZE 512**) If construct **id(a1,a2,…)** is used, arguments **a1,a2,…** will be replaced where they appear in text by corresponding arguments of macro call (eg: **#define max(A,B) ((A)>(B)?(A):(B))**means, that **x=max(p+q,r+s)** macro will be substituted for **x=(p+q)>(r+s)?(p+q):(r+s)** in the program text)
#undef *id*	Remove definition of *id*.
#if *expr* ... **#endif**	If constant expression *expr* is TRUE, statements up to **#endif** will be processed, otherwise they will not be
#if *expr* ... **#else** ... **#endif**	If constant expression *expr* is TRUE, statements up to **#else** will be processed, otherwise those between the **#else** and **#endif** will be processed
#ifdef *id* ... **#endif**	If *id* is defined (with **#define** or on the command line) statements up to **#endif** will be processed; otherwise they will not be (optional **#else** like at **#if**)
#ifndef *id* ... **#endif**	If *id* has not been defined, statements up to **#endif** will be processed; (optional **#else** like at **#if**).
#include "*file***"**	Inserts contents of *file* in program; look first in same directory as source program, then in standard places.
#include <*file***>**	Inserts contents of *file* in program; look only in standard places.
#line *n* **"***file***"**	Identifies subsequent lines of the program as coming from *file*, beginning at line *n; file* is optional.

NOTES:

Preprocessor statements can be continued over multiple lines provided each line to be continued ends with a backslash character (\). Statements can also be nested.

STORAGE CLASSES

STORAGE CLASS	DECLARED	CAN BE REFERENCED	INIT WITH	NOTES
static	outside fn	anywhere in file	constant expr	1
	inside fn/b	inside fn/b	constant expr	1
extern	outside fn	anywhere in file	constant expr	2
	inside fn/b	inside fn/b	cannot be init	2
auto	inside fn/b	inside fn/b	any expr	3
register	inside fn/b	inside fn/b	any expr	3,4,6
(omitted)	outside fn	anywhere in file or other files with ext. declaration	constant expr	5
	inside fn/b	inside fn/b	any expr	3,6

NOTES:
1. Init at start of program execution; default is zero.
2. Variable must be defined in only one place w/o **extern**.
3. Variable is init each time fn/b is entered; no default value.
4. Register assignment not guaranteed; restricted (implementation dependent) types can be assigned to registers. **&** (addr. of) operator cannot be applied.
5. Variable can be declared in only one place; initialized at start of program execution; default is zero.
6. Defaults to auto.

EXPRESSIONS

An expression is one or more terms and zero or more operators. A term can be
- *name* (function or data object)
- *constant*
- **sizeof(***type***)**
- **(***expr***)**

An expression is a constant expression if each term is a constant.

ARRAYS

A single dimension array **aname** of **n** elements of a specified type ***type*** and with specified initial values (optional) is declared with :

type **aname[n] = { val1, val2, … };**

If complete list of initial values is specified, **n** can be omitted.
Only static or global arrays can be initialized.
Char arrays can be init by a string of chars in double quotes.
Valid subscripts of the array range from **Ø** to **n-1**.
Multi dimensional arrays are declared with :

type **aname[n1][n2]… = { init_list };**

Values listed in the initialization list are assigned in 'dimension order' (i.e. as if last dimension were increasing first). Nested pairs of braces can be used to change this order if desired.

EXAMPLES:

```
/* array of char */
 static char hisname[] = {"John Smith"};
/* array of char ptrs */
 static char *days[7] =
 {"Sun", "Mon", "Tue",
  "Wed", "Thu", "Fri", "Sat"};
/* 3x2 array of ints */
 int matrix[3][2] = { {1Ø,11},{-5,Ø}, {11,21} };
/* array of struct complex */
 struct complex sensor_data[1ØØ];
```

POINTERS

A variable can be declared to be a pointer to a specified type by a statement of the form:

type ***name;**

EXAMPLES:

```
/* numptr points to floating number */
 float *numptr;
/* pointer to struct complex */
 struct complex *cp;
/* if the real part of the complex struct
   pointed to by cp is Ø.Ø */
 if (cp->real == Ø.Ø) {…}
/* ptr to char; set equal to address of
   buf[25] (i.e. pointing to buf[25]) */
 char *sptr = &buf[25];
/* store 'c' into loc ptd to by sptr */
 *sptr = 'c';
/* set sptr pointing to next loc in buf */
 ++sptr;
/* ptr to function returning int */
 int (*fptr) ();
```

FUNCTIONS

Functions follow this format :

```
ret_type name (arg1_decl, arg2_decl, ... )
   {
      local_var_decl
      statement
      ...
      return value;
   }
```

Functions can be declared **extern** (default) or **static**.
static functions can be called only from the file in which they are defined.
ret_type is the return type for the function, and can be **void** if the function returns no value.

EXAMPLE :

```
/* fn to find the length of a character string */
  int strlen (char *s)
     {
        int length = Ø;
        while ( *s++ )
           ++length;
        return length;
     }
```

STRUCTURES

A structure **sname** of specified members is declared with a statement of the form:

```
struct sname
   {
      member_declaration;
      ...
   } variable_list;
```

Each member declaration is a type followed by one or more member names.
An **n**-bit wide field **mname** is declared with a statement of the form:

type **mname:n;**

If **mname** is omitted, **n** unnamed bits are reserved; if **n** is also zero, the next field is aligned on a word boundary. **variable_list** (optional) declares variables of that structure type.
If **sname** is supplied, variables can also later be declared using the format:

struct sname variable_list;

EXAMPLE:

```
/* declare complex struct */
 struct complex
    {
       float real;
       float imaginary;
    };
/* define structures */
 struct complex c1 = { 5.Ø , Ø.Ø };
 struct complex c2, csum;
 c2 = c1; /* assign c1 to c2 */
 csum.real = c1.real + c2.real;
```

UNIONS

A union **uname** of members occupying the same area of memory is declared with a statement of the form :

```
union uname
   {
      member_declaration;
      …
   } variable_list;
```

Each member declaration is a type followed by one or more member names; **variable_list** (optional) declares variables of the particular union type. If **uname** is supplied, then variables can also later be declared using the format:

union uname variable_list;

NOTE: unions cannot be initalized.

szandi@hit.bme.hu

ENUM DATA TYPES

An enumerated data type **ename** with values **enum1,enum2,…** is declared with a statement of the form :

```
enum ename { enum1, enum2, … } variable_list;
```

The optional **variable_list** declares variables of the particular enum type. Each enumerated value is an identifier optionally followed by an equals sign and a constant expression. Sequential values starting at **Ø** are assigned to these values by the compiler, unless the **enum=value** construct is used.
If **ename** is supplied, then variables can also be declared later using the format:

```
enum ename variable_list;
```

EXAMPLES:

```
/* define boolean */
 enum boolean { false, true };
/* declare variable and inicialize value */
 enum boolean done = false;
 if (done==true) {…} /* test value */
```

FORMATTED OUTPUT

printf is used to write data to standard output (normally, your terminal). To write to a file, use **fprintf**; to 'write' data into a character array, use **sprintf**. The general format of a printf call is :

```
printf (format, arg1, arg2, … )
```

where **format** is a character string describing how **arg1,arg2,…** are to be printed. The general format of an item in the format string is :

```
%[flags][size][.prec]type
```

flags:

–	left justify value (default is right justify)
+	precede value with a + or – sign
space	precede positive value with a space
#	precede octal value with **Ø**, hex value with **Øx**; force display of decimal point for float value, and leave trailing zeros for type **g** or **G**
Ø	display leading zeros

size : is a number specifying the minimum size of the field; * instead of number means next arg (must be type of int) to printf specifies the size

prec : is the minimum number of digits to display for **int**s; number of decimal places for **e** and **f**; max. number of significant digits for **g**; max. number of chars for **s**; * instead of number means next arg (int) to printf specifies the precision

type : specifies the type of value to be displayed per the following character codes:

arg	dec.	oct.	hex.	HEX.	±d.dd	±d.dd**e**±dd
short	**hd**					
unsigned short	**hu**	**ho**	**hx**	**hX**	*default precision is 6 decimal digits*	
int	**d**					
unsigned int	**u**	**o**	**x**	**X**		
long	**ld**					
unsigned long	**lu**	**lo**	**lx**	**lX**		
float, double					**f**	**e**
long double					**Lf**	**Le**

i	same as **d**
p	a pointer, void * (implementation-defined)
n	store how many characters have been displayed, arg is int *, no output
hn	store how many characters have been displayed, arg is short *, no output
ln	store how many characters have been displayed, arg is long *, no output
E	same as **e** except display **E** before exponent instead of **e**
g	a double in **f** or **e** format, whichever takes less space w/o losing precision
G	a double in **f** or **E** format, whichever takes less space w/o losing precision
c	a char
s	a null-terminated char string (null not required if precision is given)
%	% itself

NOTES:

characters in the format string not preceded by % are literally printed;
floating point formats display both floats and doubles;
integer formats can display chars, short ints or ints.

EXAMPLE:

```
printf("%o + %#X is %+Ø*d",31,31,5,31+31);
```

Produces: `37 + ØX1F is +ØØ62`

```
printf("%f %g %#.Øf %.2g",3.14,3.14,3.14,3.14);
```

Produces: `3.14ØØØØ 3.14 3. 3.1`

FORMATTED INPUT

scanf is used to read data from standard input. To read data from a particular file, use **fscanf**. To 'read' data from a character array, use **sscanf**. The general format of a **scanf** call is :

```
scanf (format, arg1, arg2, … )
```

where **format** is a character string describing the data to be read and **arg1,arg2,…** point to where the read-in data are to be stored. The format of an item in the format string is :

```
%[*][size]type
```

* : specifies that the field is to be skipped and not assigned (i.e., no corresponding ptr is supplied in arg list)

size : a number giving the maximal size of the field

type : indicates the type of value being read :

arg is ptr to	dec.	oct.	hex.	HEX.	±d.dd *or* ±d.dd**e**±dd
short	**hd**				
unsigned short	**hu**	**ho**	**hx**	**hX**	
int	**d**				
unsigned int	**u**	**o**	**x**	**X**	
long	**ld**				
unsigned long	**lu**	**lo**	**lx**	**lX**	
float					**f,e,E,g,G**
double					**lf,le,lE,lg,lG**
long double					**Lf,Le,LE,Lg,LG**

i	same as **d**
p	pointer (same as in **printf**), arg type is void **
n	store number of chars have been matched, arg is int * , no input
hn	store number of chars have been matched, arg is short * , no input
ln	store number of chars have been matched, arg is long * , no input
c	single character, arg is char[ ]
s	string of chars terminated by a white-space character, arg is char[ ]
%	% itself
[…]	string of chars terminated by any char not enclosed between the **[** and **]**; if first char in brackets is ^, then following chars are string terminators instead.

NOTES:

A scan function returns when:
– It reaches the terminating null in the format string.
– It cannot obtain additional input characters to scan.
– A conversion fails.

Any chars in format string not preceded by **%** will literally match chars on input (e.g. `scanf("value=%d",&ival);` will match chars `"value="` on input, followed by an integer which will be read and stored in `ival`.

Whitespace in format string matches the longest possible sequence of the zero or more whitespace characters on input.

EXAMPLE:

```
sscanf("12Free of charge 21",
       "%X%c%*[^ab]%2s%d",&i,&c,text,&j);
```

will return **3** and **i=3Ø3**, **c='r'**, **text="ar"**; **j** remains unchanged.

ESCAPE CHARACTERS

\b	Backspace (*BS*)	****	Backslash (\)
\f	Form feed (*FF*)	*****nnn*	Octal character value (*n*: **Ø–7**)
\n	Newline (*NL*)	**\x***hh*	Hexadecimal character value (*h*: **Ø–9,a–f,A–F**)
\r	Carriage return (*CR*)	**\"**	Double quote (")
\t	Horizontal tab (*HT*)	**\'**	Single quote (')
\v	Vertical tab (*VT*)	**\?**	Question mark (?)
\a	Bell (*BEL*)		

LIBRARY FUNCTIONS AND MACROS

Function argument types :

```
int c; /* char */        int n,n1,n2;
unsigned int u;          long l,l1,l2;
double d,d1,d2;          char *s,*s1,*s2;
FILE *f;                 size_t su,su1,su2;
time_t tl,tl1,tl2;       fpos_t fl;
void *v,*v1,*v2;         va_list ap;
```

char and **short** are converted to **int** when passed to functions;
float is converted to **double**.

/…/ return code on error (…) return code on success

Character classification ctype.h

```
int isalnum(c)      TRUE if c is any alphanumeric char
int isalpha(c)      TRUE if c is any alphabetic char
int iscntrl(c)      TRUE if c is any control char
int isdigit(c)      TRUE if c is any decimal digit Ø–9
int isgraph(c)      TRUE if c is any printable char except space
int islower(c)      TRUE if c is any lowercase char
int isprint(c)      TRUE if c is any printable char including. space
int ispunct(c)      TRUE if c is neither a control nor alphanum. char
int isspace(c)      TRUE if c is one of the whitespace characters:
                    space, FF, NL, CR, HT, VT
int isupper(c)      TRUE if c is any uppercase char
int isxdigit(c)     TRUE if c is any hexadecimal digit Ø–9,A–F,a–f
int tolower(c)      convert c to lowercase
int toupper(c)      convert c to uppercase
```

Data conversion stdlib.h

```
double atof(s)      ASCII to double conversion /HUGE_VAL,Ø/
int atoi(s)         ASCII to int conversion
long atol(s)        ASCII to long conversion
double
  strtod(s1,*s2)    ASCII to double conversion; on return, *s2
                    points to char in s1 that terminated the scan/Ø/
long
  strtol(s1,*s2,n)  ASCII to long conversion, base n; on return, *s2
                    points to char in s1 that terminated the scan /Ø/
unsigned long
  strtoul(s1,*s2,n) ASCII to unsigned long conversion (see strtol)
```

File handling and input/output stdio.h

```
void clearerr(f)        reset error (incl. EOF) on file
int fclose(f)           close file /EOF/ (Ø)
int feof(f)             TRUE if end-of-file on f
int ferror(f)           TRUE if I/O error on f
int fflush(f)           write buffered output to f /EOF/ (Ø)
int fgetc(f)            read next char from f /EOF/
int fgetpos(f,*fl)      get the file position indicator to fl/TRUE/(Ø)
char *fgets(s,n,f)      read n–1 chars from f unless newline or end-
                        of-file reached; newline is stored in s if read
                        /NULL/
FILE *fopen(s1,s2)      open file s1, mode s2: "w"=write, "r"=read,
                        "a"=append, "b"=binary, "+"=update /NULL/
int fprintf(f,s,…)      write args to f using format s (see printf)
int fputc(c,f)          write c to f ; rtn c /EOF/
int fputs(s,f)          write s to f /EOF/ (≥Ø)
size_t fread
  (v,su1,su2,f)         read su2 data items from f into v; su1 is
                        number bytes of each item /Ø/ (bytes read/su1)
FILE
  *freopen(s1,s2,f)     close f and open s1 with mode s2 (see
                        fopen)
int fscanf(f,s,…)       read args from f using format s (see scanf)
int fseek(f,l,n)        position file pointer; if n=SEEK_SET, l is offset
                        from beginning; if n=SEEK_CUR, from current
                        pos.; if n=SEEK_END, from end of file /TRUE/ (Ø)
int fsetpos(f,*fl)      sets the file position to fl (Ø) /TRUE/
long ftell(f)           current offset from the beginning of the file /-1L/
size_t fwrite(v,su1,
  su2, f)               write su2 data items to f from v; su1 is number
                        of bytes of each item /Ø/ (bytes written/su1)
int getc(f)             read next char from f /EOF/
int getchar()           read next char from stdin /EOF/
char *gets(s)           read chars into s from stdin until newline or
                        eof reached; newline not stored /NULL/
void perror(s)          write s followed by descr. of last err. to stderr
int printf(s,…)         write args to stdout per format s; return
                        number of characters written /<Ø/
int putc(c,f)           write c to f ; rtn c /EOF/
int putchar(c)          call fputc(c,stdout)
int puts(s)             write s and newline to stdout /EOF/ (≥Ø)
int remove(s)           removes the file named s (Ø) /TRUE/
int rename(s1,s2)       rename the file named s1 to file s2 (Ø) /-1/
void rewind(f)          rewind f; calls fseek(f,ØL,SEEK_SET)

  int (*cmp)(void       comparison; cmp must return negativ if ck<ce,
  *ck, void *ce))       Ø if ck=ce, positiv if ck>ce
void qsort (void
  *base, su1, su2,      quick sort of array base (su1 elements, each
  int (*cmp)(void       su2 bytes large), using function cmp for
  *ck, void *ce))       comparison; (for cmp see bsearch)
```

String manipulation string.h

```
char *strcat(s1,s2)     concatenate s2 to end of s1; rtn s1
char *strchr(s,c)       return ptr to 1st occurence of c in s /NULL/
int strcmp(s1,s2)       compare s1 and s2; returns <Ø, Ø, >Ø if s1
                        lexicographically <s2, =s2, >s2
char *strcpy(s1,s2)     copy s2 to s1; rtn s1
size_t
  strcspn(s1,s2)        search the first s1[i] that equals any element
                        of s2; rtn i
char *strerror(n)       return a pointer to string that message
                        corrensponds to errorcode n
size_t strlen(s)        length of s (not incl. NULL)
char *strncat
  (s1,s2,su)            concatenate at most su chars from s2 to end of
                        s1; rtn s1
int
  strncmp(s1,s2,su)     compare at most su chars from s1 to s2; (see
                        strcmp)
char
  *strncpy(s1,s2,su)    copy at most su chars from s2 to s1; if s2 is
                        shorter than su, null bytes are appended; rtn s1
char
  *strpbrk(s1,s2)       searches the first s1[i] that equals any
                        element of s2; return &s1[i]
char *strrchr(s,c)      return pointer to last occurence of c in s /NULL/
size_t
  strspn(s1,s2)         search the first s1[i] that equals none of the
                        element of s2; rtn i
char *strstr(s1,s2)     search the first substring in s1 that matches s2
char *strtok(s1,s2)     break s1 into tokens delimited by s2; from the
                        second call s1=NULL; s2 may different from call
                        to call; return the ptr to token or NULL
```

Time time.h

```
char *asctime(*tm)      convert tm struct to string; rtn ptr to it
clock_t clock()         CPU time in 1.0/CLOCKS_PER_SEC seconds
                        since program startup /-1/
char *ctime(*tl)        convert time ptd to by tl to string; rtn ptr to it
double
  difftime(tl1,tl2)     difference tl1–tl2 in seconds
struct tm
  *gmtime(*tl)          convert time pointed to by tl to Universal Time
                        Coordinated (UTC) (formerly GMT)
struct tm
  *localtime(*tl)       convert time pointed to by tl to local time
time_t mktime
  (struct tm *tptr)     alters tptr to represent an equivalent encoded
                        local time /-1/
size_t strftime(
  s1, su, s2,           write tptr to buffer s1 per format s2; buffer
  struct tm *tptr)      size is su; rtn number of characters stored /Ø/
time_t time(*tl)        returns time & date in seconds; if tl<>NULL,
                        time is stored in *tl; convert time returned with
                        ctime, localtime or gmtime /-1/
```

Variable-length arguments stdarg.h

```
type
  va_arg(ap,type)       get next argument; ap must be initialized by
                        va_start; the argument type must be type
void va_end(ap)         end variable argument list
void
  va_start(ap,pN)       start variable argument list; pN is the parameter
                        just before the (...) in the function prototype
```

COMMAND LINE ARGUMENTS

Arguments typed in on the command line when a program is executed are passed to the program through **argc** and **argv**.
argc is a count of the number of arguments +1;
argv is an array of character pointers that point to each argument.
argv[Ø] points to the name of the program executed.
argv[argc] equal **NULL** pointer.
Use **sscanf** to convert arguments stored in **argv** to other data types. For example:

```
check phone 35.79
```

starts execution of a program called **check**, with :

```
argc = 3
argv[Ø] = "check"       argv[2] = "35.79"
argv[1] = "phone"       argv[3] = NULL
```

To convert number in **argv[2]**, use **sscanf**. For example :

```
int main (int argc, char *argv[])
   {  float amount;
      … sscanf (argv[2],"%f",&amount); … }
```
