

CHAPTER 2: THE STRUCTURE OF THE ATOM

A) Matter

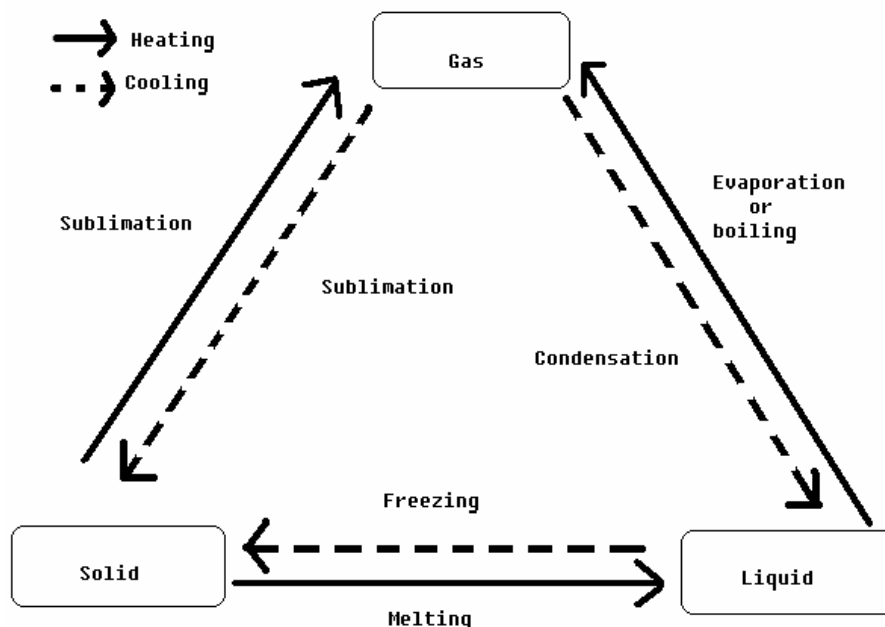

1	Matter	<ul style="list-style-type: none"> - Is anything that occupies space and has mass. - Is made up of tiny and discrete particles. - There are spaces between these particles. - These particles may be atoms, molecules or ions. - Matter exists in three states → solid, liquid and gas
2	Element	<ul style="list-style-type: none"> - Is a substance that consists of only one type of atom
3	Compound	<ul style="list-style-type: none"> - Is a substance that contains two or more elements that are chemically bonded together - Molecule, Ion
4	Atom	<ul style="list-style-type: none"> - An atom is the smallest particle of an element that can participate in a chemical reaction. - Metals and some non metals such as carbon and helium exist as atoms. - Fe, Al, Mg, Au
5	Molecule	<ul style="list-style-type: none"> - Is a group of two or more atoms which are chemically bonded together - O₂, H₂, H₂O, CO₂
6	Ion	<ul style="list-style-type: none"> - Is a positively-charged or negatively-charged particle. - Sodium Chloride, NaCl: Na⁺, Cl⁻
7	Diffusion	<ul style="list-style-type: none"> - Occur when particles of a substance, move in between the particles of another substance. - Occur most rapidly in gases, slower in liquids and slowest in solids.
8	The Kinetic Theory of Matter	
	i. Solid	
	<ul style="list-style-type: none"> - a solid has a fixed volume and shape - a solid cannot be compressed - the particles are packed closely together in an orderly manner - there are strong forces between the particles - the particles can only vibrate and rotate about their fixed positions 	
	ii. Liquid	
	<ul style="list-style-type: none"> - a liquid has fixed volume. It does not have a fixed shape but takes the shape of the container - a liquid cannot be compressed easily - The particles are packed closely together but not in orderly arrangement - The particles are held together by strong forces but weaker than the forces in a solid - The particles can vibrate, rotate and move through the liquid. They collide against each other 	

iii. Gas

- a gas does not give a fixed shape or volume
- a gas can be compressed easily
- the particles are very far apart from each other and in a random motion
- there are weak forces between the particles, the particles can vibrate, rotate and move freely. The rate of collision is greater than the rate of collision in a liquid

9 The change in the state of matter

Sublimation	Solid → Gas	Heat energy is absorbed
Melting	Solid → Liquid	Heat energy is absorbed
Evaporation or Boiling	Liquid → Gas	Heat energy is absorbed
Freezing	Liquid → Solid	Heat energy is released
Sublimation	Gas → Solid	Heat energy is released
Condensation	Gas → Liquid	Heat energy is released

1 The kinetic theory of matter

0 i. when a solid is heated,

- the particles in the solid gain kinetic energy and vibrate more vigorously
- the particles vibrate faster as the temperature increases until the energy they gained is able to overcome the forces that hold them at their fixed positions
- At this point, the solid becomes a liquid. This process is called melting.
- **Melting point is the temperature at which a solid changes into a liquid at a particular pressure**

- Example: Naphthalene $C_{10}H_8$

The heating curve of naphthalene

- The curve shows the changes in temperature when solid naphthalene melts

At point A

- naphthalene exists as solid
- When the solid is heated, heat energy is absorbed. This causes the particles to gain kinetic energy and vibrate faster
- This is why the temperature increases from point A to point B

At point B

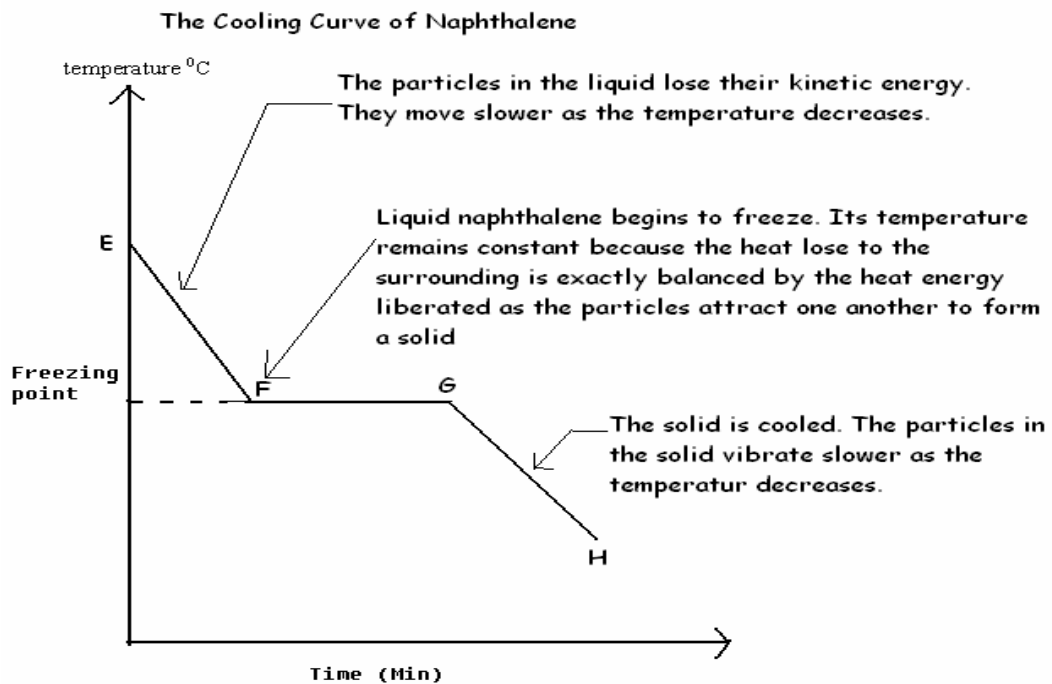

- solid naphthalene begins to melt
- during the melting process, the temperature $^{\circ}\text{C}$ of naphthalene does not rise, even though heating continues
- ***the temperature remains constant because the heat energy absorbed by the particles is used to overcome the forces between particles***
- the solid can turn into liquid
- this constant temperature is the melting point of naphthalene
- at this temperature, both solid and liquid are present

At point C

- all the solid naphthalene has melted
- from point C to D, the particles in liquid naphthalene absorb heat energy and move faster
- the temperature increases from point C to point D

ii. When a liquid is cooled / freezing

- the particles in the liquid lose energy and move slower
- As the temperature continues to drop, the particles continue to lose more energy until they do not have enough energy to move freely
- At this point, the **liquid changes into solid**. This process is called **freezing**
- **Freezing point** is the temperature at which a liquid changes into a solid at a particular pressure.
- Example: Naphthalene, acetamide

B) The Atomic Structure

1. John Dalton (1766 – 1844)

- Atom as a small, invisible ball similar to a very tiny ball

2. J.J. Thomson (1856 – 1940)

- He discovered electron
- He described the atom as sphere of positive charge which contains a few negatively charged particles called electron

3. Ernest Rutherford (1871 – 1937)

- He discovered proton, a positive charge in an atom
- The positive charge and most of the mass of the atom are concentrated in a small, central region called nucleus
- The electrons move in a space that is larger than the space occupied by the nucleus

4. Neils Bohr (18856 – 1962)

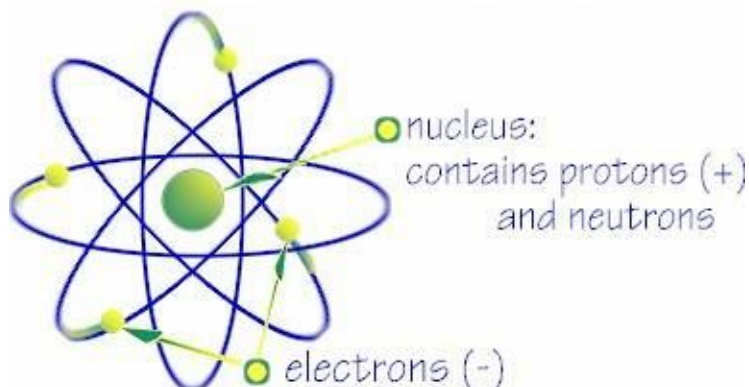

- he proposed that the electrons in an atom move in shells around the nucleus

5. James Chadwick (1891 – 1974)

- He proved the existence of neutrons, the neutral particles in the nucleus.
- Neutrons contribute approximately to half the mass of an atom

Subatomic particles of an atom

Structure of An Atom

1.	Proton	- Symbol: P Relative electric charge: +1 Relative mass: 1																																																
2.	Neutron	- Symbol: N Relative electric charge: 0 Relative mass: 1																																																
3.	Electron	- Symbol: e Relative electric charge: -1 Relative mass: Approximately $\frac{1}{1840} \sim 0.0005$																																																
4.	Nucleus	- Contain proton and neutron. - Most of the mass of an atom is concentrated in the nucleus - The nucleus has an overall positive charge due to the positively-charged protons in it																																																
5.	Proton number	- The number of proton in its atom																																																
6.	Nucleon number	- The total number of protons and neutrons in its atom - Nucleon number = number of proton + number of neutrons - Number of neutron = Nucleon number – Proton number																																																
7.	Symbols of elements	<table border="1"> <thead> <tr> <th>Element</th> <th>Symb ol</th> <th>Elemen t</th> <th>Symb ol</th> <th>Element</th> <th>Symbo l</th> <th>Elemen t</th> <th>Symb ol</th> </tr> </thead> <tbody> <tr> <td>Hydrogen</td> <td></td> <td>Carbon</td> <td></td> <td>Sodium</td> <td></td> <td>Sulphur</td> <td></td> </tr> <tr> <td>Helium</td> <td></td> <td>Nitroge n</td> <td></td> <td>Magnesi u m</td> <td></td> <td>Chlorin e</td> <td></td> </tr> <tr> <td>Lithium</td> <td></td> <td>Oxygen</td> <td></td> <td>Aluminiu m</td> <td></td> <td>Argon</td> <td></td> </tr> <tr> <td>Beryllium</td> <td></td> <td>Fluorin e</td> <td></td> <td>Silicon</td> <td></td> <td>Potassi um</td> <td></td> </tr> <tr> <td>Boron</td> <td></td> <td>Neon</td> <td></td> <td>Phosphor us</td> <td></td> <td>Calciu m</td> <td></td> </tr> </tbody> </table>	Element	Symb ol	Elemen t	Symb ol	Element	Symbo l	Elemen t	Symb ol	Hydrogen		Carbon		Sodium		Sulphur		Helium		Nitroge n		Magnesi u m		Chlorin e		Lithium		Oxygen		Aluminiu m		Argon		Beryllium		Fluorin e		Silicon		Potassi um		Boron		Neon		Phosphor us		Calciu m	
Element	Symb ol	Elemen t	Symb ol	Element	Symbo l	Elemen t	Symb ol																																											
Hydrogen		Carbon		Sodium		Sulphur																																												
Helium		Nitroge n		Magnesi u m		Chlorin e																																												
Lithium		Oxygen		Aluminiu m		Argon																																												
Beryllium		Fluorin e		Silicon		Potassi um																																												
Boron		Neon		Phosphor us		Calciu m																																												
8	Standard representati on for an atom	<table border="1"> <tbody> <tr> <td> Nucleon Number $\rightarrow A$ Proton number $\rightarrow Z$ </td> <td> X ← Symbol of element </td> <td> Nucleon Number $\rightarrow 23$ Proton number $\rightarrow 11$ </td> <td> Na ← Symbol of element </td> </tr> </tbody> </table> <p>- ${}^{19}_9F \rightarrow$ number of proton = 9, number of neutron = $19 - 9 = 10$, number of electron = 9</p>	Nucleon Number $\rightarrow A$ Proton number $\rightarrow Z$	X ← Symbol of element	Nucleon Number $\rightarrow 23$ Proton number $\rightarrow 11$	Na ← Symbol of element																																												
Nucleon Number $\rightarrow A$ Proton number $\rightarrow Z$	X ← Symbol of element	Nucleon Number $\rightarrow 23$ Proton number $\rightarrow 11$	Na ← Symbol of element																																															

		$^{12}_6\text{C}$	$^{20}_{10}\text{Ne}$	$^{39}_{19}\text{K}$	$^{80}_{35}\text{Br}$
	Number of proton				
	Number of neutron				
	Number of electron				

9. Isotopes

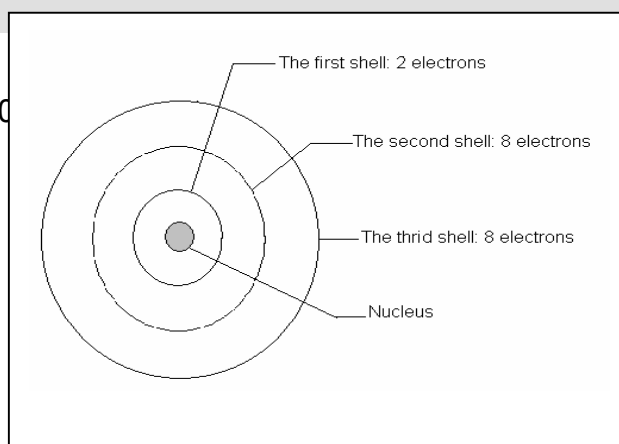

- Isotopes are atoms of the same element (same number of proton) with different number of neutrons.
- Examples: Hydrogen-1, Hydrogen-2, Hydrogen-3, Chlorine-35, Chlorine-37

Uses of Isotopes

Isotopes	Uses
Cobalt-60	☆ used in radiotherapy for the treatment of cancer
Gamma rays of cobalt-60	☆ used to destroy bacteria in food without changing the quality of food
Carbon-14	☆ estimate the age of fossils and artefacts
Phosphorous-32	☆ study the metabolism of phosphorus in plants
Sodium-24	☆ Used to detect leaks in pipes carrying gas

10 Electron arrangement

- Also known as electronic configuration
- For atoms with the proton numbers of 1 to 20
- First shell: 2 electrons
- Second shell: 8 electrons
- Third shell: 8 electrons
- Example: Cl → 2.8.7

- For atoms with more than 20 electrons, the third shell can accommodate up to 18 electrons
- Example: Rubidium, Rb → 2.8.18.8.1

11 **Valence electrons**

- Valence electrons are electrons found in the outermost occupied shell of an atom
- Example, Cl, 2.8.7. The valence electrons of a chlorine atom are 7.

Important information based on the electron arrangement

Element	Mg	Cl	K	O	Ca	Si
Proton number	12	17	19	8		
Electron arrangement	2.8.2	2.8.7	2.8.8.1	2.6		
Number of valence electron	2	7	1	6		
Number of shells	3	3	4	2		
Position in periodic table	Group 2, Period 3	Group 17, Period 3	Group 1 Period 4	Group 16 Period 2
