We don't know the exact type engine in your 900 SE but we guessed it could be the 2.3L so we used that engine type for the universal average file. Lead, regardless of the type Saab engine, should read at about 1/4th the iron level. Your lead was quite high and may show a problem at bearings. It could also be a result of having gas contamination in the oil at this level. When regularly present in an oil, the gas will soften the babbit at bearings. The other wear metals were reasonably low and show no problems. Minor moisture (not anti-freeze) found too.
