V_f limits	1.1 to 1.5	V

Notes for operation with logarithmic characteristic

This valve has a controlled linear relationship between the anode current and the logarithm of the positive grid current. This relationship holds good over a range of at least three decades of positive grid current i.e. from $3 \times 10^{-13}A$ to $3 \times 10^{-9}A$. Conditions can be established such that this change in grid current always produces a fall in anode current of $50\mu A$.

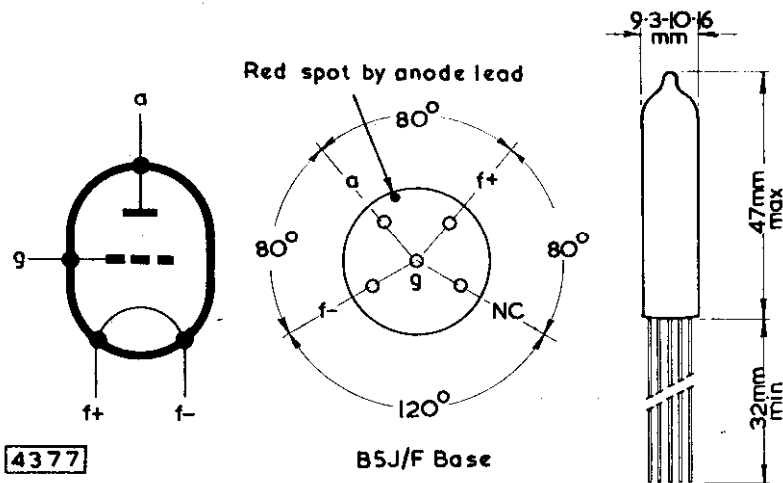

With a positive grid current of $3 \times 10^{-9}A$, the anode voltage should be set to some value (nominal 4.4V) such that when the grid current is reduced to $3 \times 10^{-13}A$ the anode current falls by $50\mu A$. It will be found that the anode voltage lies in the approx. range 3 to 6V, whilst the initial anode current is in the range 65 to $100\mu A$.

MEI404 SUBMINIATURE ELECTROMETER TRIODE

OPERATING NOTES

1. In order to avoid excessive drift of characteristics the filament voltage must be applied before the anode voltage.
2. To avoid contamination of the glass the valve should not be removed from its protective envelope until it is fitted into the equipment. Great care should be taken not to handle the valve within 13mm of the base.
3. Direct soldered connections to the leads of the valve must be at least 13mm from the seal and any bending of the leads must be 1.5mm from the seal.
4. To prevent photoemission from the grid, the valve should be operated in darkness or at a low ambient light level.

VIBRATING CAPACITOR

XL7900

QUICK REFERENCE DATA

Vibrating membrane capacitor in an evacuated envelope for use as a d.c./a.c. converter, for example in dosimeters, pH meters and electrometer equipment, where a very high input resistance is of paramount importance. Equipment capable of measuring currents as low as 500 electrons per second ($8 \times 10^{-17}A$) has been constructed, using this device.

Contact potential	-50 to +50	mV
Short term drift of contact potential	100	μV
Minimum insulation resistance	10^{15}	Ω
Maximum overall length	64.7	mm
Maximum diameter	30.2	mm

PRINCIPLE OF OPERATION (D.C. measurement)

The direct voltage to be measured is connected to capacitor C_m (measuring capacitor). The earthed membrane vibrates at its own resonance frequency (about 6kHz), due to a high frequency electric field between the electrodes of capacitor C_{dr} (driving capacitor). Thus the direct voltage on C_m is modulated at the resonance frequency of the membrane. Capacitor C_1 blocks the direct voltage from the a.c. amplifier. The output alternating voltage is proportional to the input direct voltage.

CHARACTERISTICS

Contact potential over measuring capacitor	-50 to +50	mV
Short term drift (within one day)	100	μ V
Long term drift (within one month)	1.0	mV
Temperature coefficient	20	μ V/degC

Conversion efficiency

At any given driving voltage the ratio $\frac{\text{R.M.S. output voltage}}{\text{D.C. input voltage}}$ will show a maximum spread of $\pm 60\%$.

Driving voltage

A value of high frequency driving voltage can always be found at which all capacitors have a conversion efficiency between 10 and 40% (see note 1).

Minimum insulation resistance between any two capacitor terminals (see note 2)	10^{15}	Ω
Resonance frequency of the membrane	5.3 to 6.3	kHz
Drift	1.5	%
Temperature coefficient	± 1.0	Hz/degC
Capacitances of measuring and driving capacitors	35	pF
Temperature drift	1.0	pF

RATINGS (ABSOLUTE MAXIMUM SYSTEM)

Maximum direct voltage on measuring capacitor	25	V
Maximum conversion efficiency	40	%

(Above 40% it is possible that the two capacitor plates will touch each other and will be damaged.)

SHOCK AND VIBRATION RESISTANCE

The following tests are applied to assess the mechanical quality of the tube. These conditions are not intended to be used as normal operating conditions.

Shock

The tube is subjected five times in each of four positions to an acceleration of 500g supplied by an NRL shock machine with the hammer lifted over an angle of 30° .

Vibration

The tube is subjected to a vibration of 15 to 1500Hz with an acceleration of 2.5g.

MOUNTING POSITION

Any

NOTES

- For instance, in apparatus constructed from the circuit shown in Fig. 2, it was found that all capacitors have a conversion efficiency between 10 and 40% with a voltage across L_1 of 1V r.m.s.

VIBRATING CAPACITOR

XL7900

NOTES (contd.)

2. Under standard atmospheric conditions as defined in I.E.C. publication 68-1, i.e. any combination of temperature, humidity and pressure within the following limits:

Temperature	+15 to +35	°C
Relative humidity	45 to 75	%
Pressure	860 to 1060	mbar

3. The capacitive drive opens the possibility to use as driving signal for the membrane a high frequency signal, amplitude modulated with the resonance frequency of the vibrating membrane.

Since in this case there is a great difference between the frequency of the driving signal and the modulation frequency of the voltage to be measured, the stray influences of the driving signal can easily be kept away from the measuring amplifier. In addition, a high frequency drive simplifies the design and construction of the driving oscillator.

OUTLINE DRAWING

EXAMPLE OF A DRIVING OSCILLATOR

Operating principle

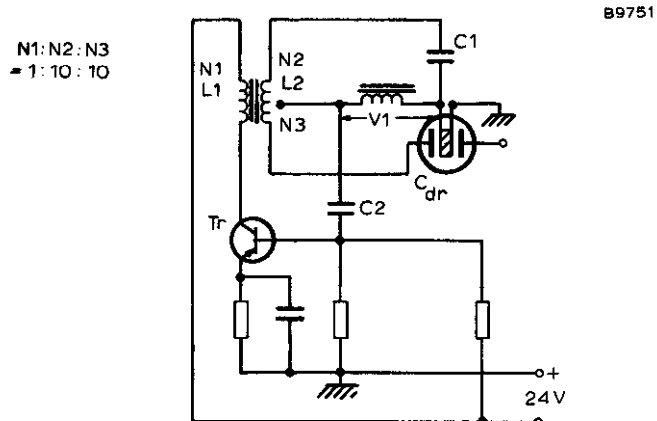

Fig. 1

The driving capacitor C_{dr} is incorporated in an impedance bridge that determines the feedback to the amplifier transistor. Capacitor C_1 has been given a slightly larger value than that of capacitor C_{dr} in its quiescent state. Due to this, the fed-back alternating voltage V_1 has the correct phase and amplitude to cause the circuit to oscillate at a frequency that is mainly determined by the network $L_2 C_1 C_{dr}$.

The electric attractive force between the capacitor plates of C_{dr} makes the membrane move towards the fixed plate of C_{dr} , as a result of which its capacitance increases, the transistor receives less feedback, and the oscillator voltage decreases.

The phases and amplitudes of the electrical and mechanical forces on the membrane, and of the feedback factor, are such that the membrane begins to vibrate at its resonance frequency and the h.f. voltage is amplitude modulated with this frequency.

Since it is very difficult to construct this circuit in such a way that stable operation is ensured, it is advisable to add components for automatic control of C_1 , as in the following circuit.
